**Description**

This invention relates to novel [3-(4-phenylpiperazin-1-yl)propyl]-, [3-(4-phenylpiperazin-1-yl)-2,2-dimethylpropyl]- and [1-(4-phenylpiperazin-1-yl-methyl)cycloprop-1-ylmethyl]-2,4(1H,3H)-pyrimidinedione, 2,4,6(1H,3H,5H)-pyrimidinetrione, 5,6-dihydro-2,4(1H,3H)-pyrimidinedione, 1,2,4-triazine-3,5(2H,4H)-dione and 5,6,7,8-tetrahydro-2,4(1H,3H)-quinazolinedione derivatives as  $\alpha_1$ -adrenoceptor antagonists, their uses as therapeutic agents, and the methods of their making.

$\alpha_1$ -Adrenoceptors mediate the contractile state of smooth muscle tissue. For example, hypersympathetic activity produces contraction of vascular smooth muscle which leads to elevated blood pressures. Thus,  $\alpha_1$ -adrenoceptor antagonists find use as anti-hypertensive agents.  $\alpha_1$ -Adrenoceptor stimulation also produces contraction of urethral and bladder neck smooth muscle, leading to increased resistance in urinary outflow. Thus,  $\alpha_1$ -adrenoceptor antagonists are useful in treating conditions which relate directly or indirectly to obstructive uropathies, particularly obstruction due to benign prostatic hyperplasia (BPH) (Lepor, H. *The Prostate Supplement*. 1990, 3, 75-84). However, the amount of  $\alpha_1$ -adrenoceptor antagonist required to produce a therapeutic effect with regard to urinary outflow, can produce an excessive decrease of blood pressure and/or an inhibition of the mechanism by which normal blood pressure is maintained during changes in posture (i.e., postural hypotension). Thus,  $\alpha_1$ -antagonists which can selectively reduce  $\alpha_1$ -adrenoceptor hyperactivity in prostatic and/or lower urinary tract smooth muscle, without affecting blood pressure or causing postural hypotension, are desirable.

In a first aspect this application relates to a compound of Formula I:

"Treating" or "treatment" of a disease includes:

(1) preventing the disease from occurring in an animal which may be predisposed to the disease but does not yet experience or display symptoms of the disease,

40 (2) inhibiting the disease, i.e., arresting its development, or

(3) relieving the disease, i.e., causing regression of the disease.

45 Isomerism is the phenomenon wherein compounds have identical molecular formulae but differ in the nature or sequence of bonding of their atoms or in the arrangement of their atoms in space. Isomers that differ in the arrangement of their atoms in space are termed "stereoisomers". Stereoisomers that are not mirror images of one another are termed "diastereomers" and stereoisomers that are nonsuperimposable mirror images are termed "enantiomers" or sometimes optical isomers. A carbon atom bonded to four nonidentical substituents is termed a "chiral center".

50 A compound with one chiral center has two enantiomeric forms of opposite chirality and may exist as either an individual enantiomer or as a mixture of enantiomers. A mixture containing equal amounts of individual enantiomeric forms of opposite chirality is termed a "racemic mixture". A compound that has more than one chiral center has 2<sup>n-1</sup> enantiomeric pairs, where *n* is the number of chiral centers. Compounds with more than one chiral center may exist as either an individual diastereomer or as a mixture of diastereomers, termed a "diastereomeric mixture".

55 When one chiral center is present a stereoisomer may be characterized by the absolute configuration of that chiral center. Absolute configuration refers to the arrangement in space of the substituents attached to the chiral center. The substituents attached to the chiral center under consideration are ranked in accordance with the *Sequence Rule* of Cahn, Ingold and Prelog and the absolute descriptor *R* or *S* is cited in parentheses followed by a hyphen and the chemical name of compound.

Compounds of Formula I can exist as individual stereoisomers or mixtures of stereoisomers. For example, compounds of Formula I in which R<sup>5</sup> is a group of Formula (c) or (d) can contain chiral centers at the 5- and/or 6-positions of the 5,6-dihydro-2,4(1H,3H)-pyrimidinedione moiety. When chiral centers are present at both the 5- and 6-positions two enantiomeric pairs are possible (i.e., the 5R,6S/5S,6R enantiomeric pair, also referred to as the *cis*-isomers, and the 5R,6R/5S,6S enantiomeric pair, also referred to as the *trans*-isomers). For the purposes of the present application when referring to a compound of Formula I by name or by formula and the configuration is not designated, it is to be understood that the reference is to all possible configurations of the compound.

The compounds of Formula I are named in accordance with acceptable nomenclature rules generally consistent with "Chemical Abstracts". For example, the compound of Formula I in which R<sup>1</sup> is methoxy and R<sup>2</sup>, R<sup>3</sup> and R<sup>4</sup> are each hydro:

is named 3-[3-[4-(2-methoxyphenyl)piperazin-1-yl]propyl]-5-methyl-2,4(1H,3H)-pyrimidinedione when R<sup>5</sup> is a group of Formula (a), wherein Z is CH and R<sup>7</sup> is methyl;  
 is named 3-[3-[4-(2-methoxyphenyl)piperazin-1-yl]propyl]-5,6,7,8-tetrahydro-2,4(1H,3H)-quinazolinedione when R<sup>5</sup> is a group of Formula (a), wherein Z is C(R<sup>9</sup>) and R<sup>7</sup> and R<sup>9</sup> together are tetramethylene;  
 is named 4-[3-[4-(2-methoxyphenyl)piperazin-1-yl]propyl]-6-methyl-1,2,4-triazine-3,5(2H,4H)-dione when R<sup>5</sup> is a group of Formula (a), wherein Z is N and R<sup>7</sup> is methyl; and is named 3-[3-[4-(2-methoxyphenyl)piperazin-1-yl]propyl]-5,5-dimethyl-2,4,6(1H,3H,5H)-pyrimidinetrione when R<sup>5</sup> is a group of Formula (c) and each R<sup>8</sup> is methyl.

#### PHARMACOLOGY AND UTILITY:

The  $\alpha_1$ -adrenoceptor pharmacology of the compounds of this invention was determined by art-recognized procedures. *In vitro* assays for measuring the relative effect of test compounds on  $\alpha_1$ -adrenoceptor mediated contraction of rat isolated aortic and rabbit isolated urinary bladder smooth muscle are described in Example 38. *In vitro* assays for measuring the relative effect of test compounds on  $\alpha_1$ -adrenoceptor mediated contraction of human isolated arterial, prostatic and urinary bladder smooth muscle are described in Example 39. An *in vivo* assay for measuring the blood pressure lowering effects of test compounds in normotensive and spontaneously hypertensive rats is described in Example 40. An *in vivo* assay for measuring the effect of test compounds on the reflex maintenance of basal blood pressure in response to postural change from supine to vertical is described in Example 41. An *in vivo* assay for measuring the relative effect of test compounds on  $\alpha_1$ -adrenoceptor mediated increases in blood and intraurethral pressures is described in Example 42.

In summary, the compounds of this invention were tested by the procedures described above and found to selectively inhibit the  $\alpha_1$ -adrenoceptors which mediate the contractile state of prostatic and lower urinary tract smooth muscle. The compounds of this invention will decrease resistance in urinary outflow, without producing the blood pressure lowering effects and/or the postural hypotension that are associated with previously described  $\alpha_1$ -adrenoceptor antagonists. Accordingly, the compounds of this invention are useful in treating conditions which relate directly or indirectly to

obstructive uropathies, particularly obstruction due to benign prostatic hyperplasia.

ADMINISTRATION AND PHARMACEUTICAL COMPOSITION:

5 In general, compounds of Formula I will be administered in therapeutically effective amounts via any of the usual and acceptable modes known in the art, either singly or in combination with another compound of Formula I or with another therapeutic agent. A therapeutically effective amount may vary widely depending on the severity of the disease, the age and relative health of the subject, the potency of the compound used and other factors. Therapeutically effective amounts of compounds of Formula I may range from 0.1 micrograms per kilogram body weight ( $\mu\text{g}/\text{kg}$ ) per day to 1 milligram per kilogram body weight ( $\text{mg}/\text{kg}$ ) per day, typically 1  $\mu\text{g}/\text{kg}/\text{day}$  to 10  $\mu\text{g}/\text{kg}/\text{day}$ . Therefore, a therapeutically effective amount for a 80 kg human may range from 8  $\mu\text{g}/\text{day}$  to 800  $\mu\text{g}/\text{day}$ , typically 80  $\mu\text{g}/\text{day}$  to 0.8 mg/day.

10 One of ordinary skill in the art of treating such diseases will be able, without undue experimentation and in reliance upon personal knowledge and the disclosure of this application, to ascertain a therapeutically effective amount of a compound of Formula I for a given disease.

15 In general, compounds of Formula I will be administered as pharmaceutical compositions by one of the following routes: oral, systemic (e.g., transdermal, intranasal or by suppository) or parenteral (e.g., intramuscular, intravenous or subcutaneous). Compositions can take the form of tablets, pills, capsules, semisolids, powders, sustained release formulations, solutions, suspensions, elixirs, aerosols, or any other appropriate composition and are comprised of, in general, a compound of Formula I in combination with at least one pharmaceutically acceptable excipient. Acceptable 20 excipients are non-toxic, aid administration, and do not adversely affect the therapeutic benefit of the compound of Formula I. Such excipient may be any solid, liquid, semisolid or, in the case of an aerosol composition, gaseous excipient that is generally available to one of skill in the art.

25 Solid pharmaceutical excipients include starch, cellulose, talc, glucose, lactose, sucrose, gelatin, malt, rice, flour, chalk, silica gel, magnesium stearate, sodium stearate, glycerol monostearate, sodium chloride, dried skim milk, and the like. Liquid and semisolid excipients may be selected from water, ethanol, glycerol, propylene glycol and various oils, including those of petroleum, animal, vegetable or synthetic origin (e.g., peanut oil, soybean oil, mineral oil, sesame oil, etc.). Preferred liquid carriers, particularly for injectable solutions, include water, saline, aqueous dextrose and glycols.

35 in which L is a leaving group and each R<sup>1</sup>, R<sup>2</sup>, R<sup>3</sup>, R<sup>4</sup> and R<sup>5</sup> are as defined in the Summary of the Invention with respect Formula I.

40 In general, compounds of Formula I can be prepared by alkylating an optionally substituted 1-phenylpiperazine of Formula 2 with a compound of Formula 3, or a protected derivative thereof, and then deprotecting when necessary. The alkylation can be carried out neat at 100 to 250°C, typically at 150 to 200°C and preferably at 180 to 190°C, requiring 1 to 3 hours (for further details see Example 24, *infra*). Alternatively, the reaction can be carried out in a suitable inert organic solvent (e.g., acetonitrile, *N,N*-dimethylformamide (DMF), *N*-methylpyrrolidone (NMP), any appropriate mixture of suitable solvents, etc., preferably acetonitrile) with a suitable base present (e.g., sodium carbonate, potassium carbonate, cesium carbonate, 2,4,6-trimethylpyridine, etc., preferably potassium carbonate) and optionally an iodide salt present (e.g., sodium iodide, lithium iodide, tetraalkylammonium iodides such as tetramethylammonium iodide and the like, etc., preferably sodium iodide) at 40 to 90°C, typically at 70 to 85°C and preferably at reflux, requiring 6 to 72 hours (for further details see Example 25, *infra*).

50 Deprotection when a nitrogen protective group is present can be effected by any means which removes the protective group and gives the desired product in reasonable yield. A detailed description of the techniques applicable to protective groups and their removal can be found in T.W. Greene, *Protective Groups in Organic Synthesis*, John Wiley & Sons, Inc. 1981. For example, a convenient method of deprotection when the protective group is 2-(trimethylsilyl)ethoxymethyl is carried out with tetrabutylammonium fluoride in a suitable inert organic solvent (e.g., tetrahydrofuran (THF), hexamethylphosphoramide (HMPA), any appropriate mixture of suitable solvents, etc., preferably THF) at 10 to 65°C, typically at 20 to 25°C and preferably at approximately 25°C, and requires 8 to 24 hours (for further details see Example 27, *infra*). Deprotection when the protective group is methoxymethyl can be effected with concentrated hydrochloric acid in a suitable solvent, typically water/alcohol (9:1-1:9) mixture (e.g., water/methanol, /ethanol, /isopropanol, /any appropriate mixture of suitable alcohols, etc.) and preferably water/isopropanol (7:1), at 20 to 100°C, typically at

70 to 90°C and preferably at approximately reflux, requiring 2 to 14 hours.

In addition, any hydroxy groups present in the compound of Formula 2 or 3 should be protected with a suitable protective group (e.g., benzyl, *para*-methoxybenzyl, 1-naphthylmethyl, etc., preferably benzyl). A convenient method of deprotecting a benzyl protected hydroxy group is by catalytic hydrogenation. The hydrogenation is carried out with a suitable catalyst (e.g., 10% palladium on carbon (10% Pd/C), palladium hydroxide, palladium acetate, etc. preferably 10% Pd/C) in the presence of ammonium formate and in an appropriate solvent, typically an alcohol (e.g., ethanol, methanol, isopropanol, any appropriate mixture of alcohols, etc.) and preferably methanol, at 50 to 66°C, typically at 63 to 66°C and preferably at reflux. Alternatively, the benzyl group is removed by treating the protected compound with the catalyst under a hydrogen atmosphere at 0 to 50 psi, typically at 10 to 20 psi and preferably at approximately 15 psi, at 10 to 50°C, typically at 23 to 27°C and preferably at 25°C.

An alternative method for preparing compounds of Formula I comprises alkylating a compound of the formula H-R<sup>5</sup> (Formula 4), or the protected derivative thereof, with a compound of Formula 5 and then deprotecting when necessary. The deprotection is carried out as set forth in Reaction Scheme I.

Alternatively, the alkylation of the compound of Formula 4 is effected by treating the compound of Formula 4 with a suitable silylating agent (e.g., 1,1,1,3,3,3-hexamethyldisilazane (HMDS), *N*,*O*-bistrimethylsilylacetamide, hexamethylsiloxane, etc., preferably HMDS) in a suitable inert organic solvent (e.g., trifluoromethanesulfonic acid, DMF, NMP, THF, DME, toluene, any appropriate mixture of suitable solvents, etc., preferably trifluoromethanesulfonic acid) at 100 to 180°C, typically at 150 to 180°C and preferably at approximately 90°C, for 6 to 24 hours and then reacting with 1 molar equivalent of the compound of Formula 5 neat or in a suitable inert organic solvent (e.g., trifluoro-methanesulfonic acid,

dry benzene, toluene, 1,2-dichlorobenzene, any appropriate mixture of suitable solvents, etc., preferably trifluoromethanesulfonic acid) at 60 to 150°C, typically at 60 to 110°C and preferably at approximately 70°C, for 0.25 to 15 hours. Proceeding as described above the following compound of Formula I was prepared:

A convenient method of deprotection when the protective group is benzyl is by treating with a suitable catalyst (e.g., 10% palladium on carbon (10% Pd/C), palladium hydroxide, palladium acetate, etc. preferably 10% Pd/C) under a hydrogen atmosphere at 0 to 50 psi, typically at 10 to 20 psi and preferably at approximately 15 psi, and in an appropriate solvent, typically an alcohol (e.g., ethanol, methanol, isopropanol, any appropriate mixture of alcohols, etc.) and preferably methanol, at 20 to 50°C, typically at 23 to 27°C and preferably at 25°C. Further details of the reaction steps set forth in this and the preceding paragraph are provided in Example 16, infra.

A convenient method for preparing a compound of Formula 2 in which R<sup>1</sup> is pyrrol-1-yl comprises reacting a protected 4-(2-aminophenyl)piperazine, preferably 4-(2-aminophenyl)piperazine-1-carbaldehyde, with 2,5-dimethoxytetrahydrofuran and then deprotecting. The reaction with the 1-carbaldehyde is carried out in a suitable solvent, typically an acid (e.g., concentrated acetic acid, propionic acid, trifluoroacetic acid, any appropriate mixture of suitable acids, etc.) and preferably concentrated acetic acid, at 100 to 150°C, typically at 110 to 120°C and preferably at reflux, and requires 1 to 3 hours. The 4-(2-aminophenyl)piperazine-1-carbaldehyde can be prepared by reacting 1-chloro-2-nitrobenzene with piperazine-1-carbaldehyde to give 4-(2-nitro-phenyl)piperazine-1-carbaldehyde and then reducing. The reaction between the 1-carbaldehyde and the 2-nitrobenzene is carried out in a suitable solvent (e.g., DMF, NMP, acetonitrile, any appropriate mixture of suitable solvents, etc., preferably DMF) at 50 to 100°C, typically at 60 to 80°C and preferably at approximately 100°C, and requires 20 to 50 hours. The reaction is carried out in a suitable solvent (e.g., water, ethanol, 2-methoxyethanol, any appropriate mixture of suitable solvents, etc., preferably water) at 30 to 100°C, typically at 50 to 70°C and preferably at approximately 60°C, and requires 0.1 to 2 hours (for further details see Example 1, infra.).

Protected compounds of Formula 4 in which R<sup>5</sup> is a group of Formula (a) can be prepared by reacting a corresponding compound of Formula 4 in which R<sup>6</sup> is hydro with a suitable protecting agent (e.g., 2-(trimethylsilyl)ethoxymethyl chloride, di-*tert*-butyldicarbonate, etc.). For example, a protected compound of Formula 4 wherein the protective group is 2-(trimethylsilyl)ethoxymethyl can be prepared by reacting the unprotected compound with 2-(trimethylsilyl)ethoxy-methyl chloride in the presence of a suitable base (e.g., diisopropylethylamine, diethylaniline, potassium carbonate, sodium hydride, etc., preferably sodium hydride) in a suitable solvent (e.g., methylene chloride, THF, DMF, NMP, etc., preferably DMF) at 0 to 30°C, typically at 20 to 30°C and preferably at approximately 22°C, requiring 1 to 16 hours (for further details see Example 7, infra.).

A compound of Formula 4 in which R<sup>5</sup> is a group of Formula (a) wherein Z is C(R<sup>9</sup>), R<sup>7</sup> and R<sup>9</sup> together are —(CH<sub>2</sub>)<sub>4</sub>— and R<sup>9</sup> is hydro (i.e., 5,6,7,8-tetrahydro-2,4(1H,3H)-quinazolinedione) can be prepared by hydrolyzing 4-

ethoxy-5,6,7,8-hexahydro-2(3H)-quinazolineone. The hydrolyzation is carried out with acid (e.g., hydrochloric acid) in a suitable solvent, typically an alcohol (e.g., ethanol, methanol, isopropanol, any appropriate mixture of alcohols, etc.) and preferably ethanol, at 50 to 85°C, typically at 60 to 70°C and preferably at approximately 65°C, and requires 0.5 to 5 hours (for further details see C. Bischoff and E. Schröder, *J. f. prakt. Chemie* 1985, 327, 129-132). The 4-ethoxy-5,6,7,8-hexahydro-2(3H)-quinazolineone is prepared by reacting ethyl 2-oxocyclohexanecarboxylate with cyanamide. The reaction with the cyanamide is carried out in a suitable solvent, typically an alcohol (e.g., ethanol, methanol, isopropanol, any appropriate mixture of alcohols, etc.) and preferably ethanol, at 25 to 100°C, typically at 50 to 80°C and preferably at approximately 75°C, and requires 1 to 40 hours.

Compounds of Formula 4 in which R<sup>5</sup> is a group of Formula (b) can be prepared by alkylating a corresponding compound of the formula P-R<sup>5</sup> in which P is a protective group (e.g., benzyl, 2-(trimethylsilyl)ethoxymethyl, *tert*-butyloxycarbonyl, etc.) and R<sup>5</sup> is a group of Formula (b) wherein R<sup>6</sup> is hydro with an appropriate alkylating agent (e.g., iodomethane, benzyl bromide, 4-methylbenzyl bromide, cyclohexylmethyl bromide, pyrazin-2-ylmethyl bromide, thien-2-ylmethyl bromide, fur-3-ylmethyl bromide, biphenyl-2-ylmethyl bromide, etc.) and then deprotecting. In a similar fashion, a compound of Formula 4 in which R<sup>5</sup> is a group of Formula (b) and R<sup>6</sup> is benzyl can be prepared by alkylating a corresponding compound of Formula 4 in which R<sup>6</sup> is hydro with benzyl bromide and then deprotecting.

The alkylation is carried out with at least 2 molar equivalents of the alkylating agent in the presence of an excess amount of a suitable base (e.g., sodium carbonate, potassium carbonate, cesium carbonate, sodium hydride, etc., preferably sodium hydride) and in a suitable solvent (e.g., DMF, NMP, THF, DME, any appropriate mixture of suitable solvents, etc., preferably DMF) at 20 to 80°C, typically at 30 to 50°C and preferably at approximately 50°C, requiring 4 to 40 hours.

The deprotection can be effected by any means which removes the protective group without removing the radical designated by R<sup>6</sup>. For example, deprotection when the protective group is benzyl can be effected under conditions similar to those described above for de-benzylating a compound of Formula 3 in which R<sup>6</sup> is benzyl (for further details see Example 9, *infra*). Deprotection when the protective group is 2-(trimethylsilyl)ethoxymethyl can be effected under the conditions described above for deprotecting a similarly protected compound of Formula I.

Compounds Formula 4 in which R<sup>7</sup> is hydroxymethyl can be prepared by reacting a corresponding compound of Formula 4 in which R<sup>7</sup> is hydro with paraformaldehyde. The reaction is carried out in the presence of an aqueous base (e.g., aqueous sodium hydroxide, aqueous potassium hydroxide, etc.) at 20 to 100°C, typically at 40 to 60°C and preferably at approximately 50°C, and requires 40 to 90 hours (for further details see Example 3, *infra*).

Compounds of Formula 4 in which R<sup>7</sup> is hydroxyiminomethyl can be prepared by converting a corresponding compound of Formula 4 in which R<sup>7</sup> is hydro to a 2,4-dioxo-5(1H,3H)-pyrimidinecarbaldehyde derivative via a modified Reimer-Tiemann reaction (see Gupta, V.S. and Huennekens, F.M. (1967), *Biochemistry*, 6(7), 2168) and then reacting the carbaldehyde with hydroxylamine hydrochloride. The conversion to the carbaldehyde is carried out with chloroform in the presence of aqueous sodium hydroxide at 10 to 100°C, typically at 60 to 80°C and preferably at reflux, and requires 0.5 to 15 hours. The reaction with the hydroxylamine hydrochloride is carried out in the presence of potassium acetate in a suitable solvent (e.g., water, methanol, 1/1 water/methanol, any appropriate mixture of suitable solvents, etc., preferably a 1/1 water/methanol) at 20 to 100°C, typically at 60 to 90°C and preferably at reflux, and requires 0.2 to 5 hours. Further details of the reaction steps set forth above are provided in Example 4, *infra*).

Compounds of Formula 4 in which R<sup>6</sup> is optionally substituted aryl or heteroaryl can be prepared by reacting a compound of Formula 4 in which R<sup>6</sup> is hydro with an appropriate alkylating agent (e.g., 1-fluoro-4-iodobenzene, bromobenzene, 2-bromopyridine, etc.) in the presence of a suitable copper source (e.g., copper(I) oxide, copper bronze, copper(I) bromide, etc., preferably copper(I) oxide) in a suitable inert organic solvent (e.g., 2,4,6-trimethylpyridine, diethylaniline, NMP, any appropriate mixture of suitable solvents, etc., preferably 2,4,6-trimethylpyridine) at 100 to 180°C, typically at 150 to 175°C and preferably at reflux, requiring 4 to 20 hours (for further details see Example 8, *infra*).

Compounds of Formula 4 in which R<sup>5</sup> is a group of Formula (c) wherein X is C(O) can be prepared by reacting a compound of the formula H<sub>2</sub>NC(O)NHR<sup>6</sup> (e.g., urea, benzylurea, etc.) with an alkyl malonate of the formula (R<sup>8</sup>)<sub>2</sub>C(COOR)<sub>2</sub>, wherein each R<sup>6</sup> and R<sup>8</sup> are as defined in the Summary of the Invention with respect to Formula I. The reaction is carried out in the presence of a base (e.g., sodium methoxide, potassium *tert*-butoxide, sodium hydride, etc. preferably sodium methoxide) in a suitable solvent, typically an alcohol (e.g., ethanol, methanol, isopropanol, any appropriate mixture of alcohols, etc.) and preferably methanol, at 50 to 100°C, typically at 60 to 70°C and preferably at reflux (for further details see Example 10, *infra*).

#### Compounds of Formula 5:

In general, compounds of Formula 5 are prepared by reacting a compound of Formula 2 with a compound of Formula 8. The reaction is carried out in the presence of a suitable base (e.g., sodium carbonate, potassium carbonate, cesium carbonate, sodium hydride, etc., preferably potassium carbonate) and in a suitable inert organic solvent (e.g., acetonitrile, DMF, NMP, any appropriate mixture of suitable solvents, etc., preferably acetonitrile) at 50 to 85°C, typically at 70 to 80°C and preferably at reflux, and requires 2 to 16 hours (for further details see Example 28, *infra*).

Compounds of Formula 5 in which L is hydroxy and R<sup>3</sup> and R<sup>4</sup> are both methyl can be prepared by acylating a compound of Formula 2 with a protected 3-hydroxy-2,2-dimethylpropionyl halide (e.g., 3-benzyloxy-2,2-dimethylpropionyl chloride) to give the corresponding protected 3-hydroxy-2,2-dimethyl-1-(4-phenyl-piperazin-1-yl)-1-propanone and then reducing and deprotecting to give the corresponding 2,2-dimethyl-3-(4-phenylpiperazin-1-yl)-1-propanol. The acylation is carried out in a suitable solvent (e.g., benzene, methylene chloride, any appropriate mixture of suitable solvents, etc.) and requires 0.1 to 6 hours at approximately 0°C. The reduction can be effected with a suitable chemical reducing agent (e.g., lithium aluminum hydride, etc.) in a suitable solvent (e.g., THF, any appropriate mixture of suitable solvents, etc.) requiring 1 to 30 hours at reflux. Deprotection when the protective group is benzyl is conveniently carried out by phase-transfer catalytic hydrogenation (e.g. ammonium formate, Pd/C; etc.) in a suitable solvent, typically an alcohol (e.g., methanol, any appropriate mixture of suitable alcohols, etc.), for 2 to 14 hours at reflux. The 1-propanol can be converted to the corresponding 1-chloro-2,2-dimethyl-3-(4-phenylpiperazin-1-yl)propane by reacting it with a suitable halogenating agent (e.g., *p*-toluenesulfonyl chloride, etc.) in a suitable solvent (e.g., methylene chloride, pyridine, any appropriate mixture of suitable solvents, etc.) requiring 0.1 to 12 hours at approximately 25°C.

The protected 3-hydroxy-2,2-dimethylpropionyl halide is prepared by methylating ethyl cyanoacetate to give 2-cyano-2-methylpropionic acid, reducing the propionic acid and protecting to give protected 3-hydroxy-2,2-dimethylpropanenitrile, hydrolyzing the protected 3-hydroxy-2,2-dimethylpropanenitrile to give protected 3-hydroxy-2,2-dimethylpropionic acid and then converting the propionic acid to a corresponding acid halide. The methylation can be effected with a suitable methylating agent (e.g., iodomethane, etc.) in the presence of a base (e.g., triethylbenzyl ammonium hydroxide, etc.) in a suitable solvent (e.g., water, any appropriate mixture of suitable solvents, etc.) requiring 1 to 12 hours at approximately 20°C. The reduction is carried out by reacting the propionic acid with methyl chloroformate for 0.1 to 2 hours at -5 to 0°C and then reacting with a suitable chemical reducing agent (e.g., sodium borohydride, etc.) in a suitable solvent (e.g., THF, any appropriate mixture of suitable solvents, etc.) for 1 to 4 hours at approximately 20°C. Protecting wherein the protective group is benzyl can be effected by reacting the unprotected 3-hydroxy-2,2-dimethylpropanenitrile with benzyl bromide for 1 to 4 hours at approximately -5°C. The hydrolyzation can be effected with an aqueous base (e.g., 10% sodium hydroxide, etc.) in a suitable solvent, typically an alcohol (e.g., methanol, any appropriate mixture of suitable alcohols, etc.), for 2 to 12 hours at reflux. Conversion to the acid halide can be effected with a suitable halogenating agent (e.g., oxalyl chloride, etc.) in a suitable solvent (e.g., benzene, methylene chloride, any appropriate mixture of suitable solvents, etc.) requiring 1 to 6 hours at approximately 25°C. Further details of the reaction steps set forth in this and the preceding paragraph are provided in Example 29, infra.

Compounds of Formula I may be prepared as pharmaceutically acceptable acid addition salts by reacting the free base forms of a compound of Formula I with a pharmaceutically acceptable inorganic or organic acid. Alternatively, the pharmaceutically acceptable base addition salts of compounds of Formula I may be prepared by reacting the free acid forms of compounds of Formula I with pharmaceutically acceptable inorganic or organic bases. Inorganic and organic acids and bases suitable for the preparation of the pharmaceutically acceptable salts of compounds of Formula I are set forth in the definitions section of this application. Alternatively, the salt forms of the compounds of Formula I may be prepared using salts of the starting materials or intermediates.

The free acid or free base forms of the compounds of Formula I can be prepared from the corresponding base addition salt or acid addition salt form. For example, compounds of Formula I in an acid addition salt form may be converted to the corresponding free base by treating with a suitable base (e.g., ammonium hydroxide solution, sodium hydroxide, etc.). Compounds of Formula I in a base addition salt form may be converted to the corresponding free acid by treating with a suitable acid (e.g., hydrochloric acid, etc.).

The N-oxides of the compounds of Formula I can be prepared by treating an unoxidized form of the compound of Formula I with an oxidizing agent (e.g., trifluoroperacetic acid, permaleic acid, perbenzoic acid, peracetic acid, *meta*-chloroperoxybenzoic acid, etc.) in a suitable inert organic solvent (e.g., a halogenated hydrocarbon such as methylene chloride) at approximately 0°C. Alternatively, the N-oxides of the compounds of Formula I can be prepared from the N-oxide of an appropriate starting material.

Compounds of Formula I in unoxidized form can be prepared from N-oxides of compounds of Formula I by treating with a reducing agent (e.g., sulfur, sulfur dioxide, triphenyl phosphine, lithium borohydride, sodium borohydride, phosphorus trichloride, tribromide, etc.) in an suitable inert organic solvent (e.g., acetonitrile, ethanol, aqueous dioxane, etc.) at 0 to 80°C.

As will be apparent to one of ordinary skill in the art, compounds of Formula I may be prepared as individual isomers or mixtures of isomers. Isomers which are diastereomers have distinct physical properties (e.g., melting points, boiling points, solubilities, reactivity, etc.) and are readily separated by taking advantage of these dissimilarities. For example, diastereomers can be separated by chromatography or, preferably, by separation/resolution techniques based upon differences in solubility. Optical isomers can be separated by reacting the racemic mixture with an optically active resolving agent to form a pair of diastereomeric compounds. The isomers are then separated by any of the techniques described above for the separation of diastereomers and the pure optical isomer recovered, along with the resolving agent, by any practical means that would not result in racemization. While resolution of optical isomers can be carried out using covalent diastereomeric derivatives of compounds of Formula I, dissociable complexes are preferred, e.g., crystalline diastereomeric salts. Suitable resolving acids include tartaric acid, o-nitrotartranilic acid, mandelic acid, malic acid, the 2-arylpropionic acids in general, and camphorsulfonic acid.

Individual isomers of compounds of Formula I can also be separated by such methods as direct or selective crystallization or by any other method known to one of ordinary skill in the art. A more detailed description of the techniques applicable to the resolution of stereoisomers of compounds of Formula I can be found in Jean Jacques, Andre Collet, Samuel H. Wilen, Enantiomers, Racemates and Resolutions, John Wiley & Sons, Inc. (1981). Alternatively, individual isomers of compounds of Formula I can be prepared using the isomeric forms of the starting materials.

In summary, an aspect of this invention is a process for preparing a compound of Formula I:

Example 35A

*cis*-3-(3-[4-[4-Fluoro-2-(2,2,2-trifluoroethoxy)phenyl]piperazin-1-yl]propyl)-5,6-dihydroxy-5-methyl-5,6-dihydro-2,4(1H,3H)-pyrimidinedione fumarate, prepared as above, was dissolved in ethanol to a concentration of 20 mg/ml. A 2.0 ml fraction was injected onto a Chiraldak AS (2 x 250 cm) column, and was eluted with hexane/ethanol/diethylamine (90:9.9:0.1) at 8.0 ml/min, monitoring the eluate by UV absorption at 238 nm. The (+)-enantiomer eluted first, and the (-)-enantiomer second.

After repeated injections and elutions, the fractions highly enriched in the (+)-enantiomer were pooled and concentrated to give 610 mg (1.28 mmol) of the free base. This material was dissolved in warm methanol (10 ml), and fumaric acid (148 mg, 1.28 mmol) added and dissolved. A suspension of a fine powder was obtained on the addition of ethyl acetate (15 ml). The suspension was aged at room temperature, filtered and dried in vacuo, and the solids recrystallized to give 400 mg of the (+)-enantiomer of *cis*-3-(3-[4-[4-fluoro-2-(2,2,2-trifluoroethoxy)phenyl]piperazin-1-yl]propyl)-5,6-dihydroxy-5-methyl-5,6-dihydro-2,4(1H,3H)-pyrimidinedione fumarate: m.p. 183.5-192.1°C, [α]<sub>D</sub> +13.2° (c=0.34, MeOH). The product was analyzed using an analytical Chiraldak AS column, and found to consist of 94.9% (+)-enantiomer and 5.1% (-)-enantiomer.

Similarly, the fractions highly enriched in the (-)-enantiomer were pooled and concentrated to give 540 mg of the free base. This material was dissolved in warm methanol (10 ml), and fumaric acid (130 mg) added and dissolved. A suspension of a fine powder was obtained on the addition of ethyl acetate (15 ml). The suspension was aged at room temperature, filtered and dried in vacuo, to give 356 mg of the (-)-enantiomer of *cis*-3-(3-[4-[4-fluoro-2-(2,2,2-trifluoroethoxy)phenyl]piperazin-1-yl]propyl)-5,6-dihydroxy-5-methyl-5,6-dihydro-2,4(1H,3H)-pyrimidinedione fumarate: m.p. 169.5-178.0°C, [α]<sub>D</sub> -15.6° (c=0.48, MeOH). EXAMPLE 38 *$\alpha_1$ -Adrenoceptor In Vitro, Functional Assay in Tissue Isolated from Rabbit and Rat*

5 The following describes *in vitro* assays for measuring the relative effect of test compounds on  $\alpha_1$ -adrenoceptor mediated contraction of rat, isolated aortic smooth muscle and rabbit, isolated urinary bladder smooth muscle.

10 Thoracic aorta were isolated from rats and immediately immersed in Krebs' solution (comprising in mM concentrations: NaCl, 118.5; NaHCO<sub>3</sub>, 25; dextrose, 5; KCl, 4.8; CaCl<sub>2</sub>, 2.5; MgSO<sub>4</sub>, 1.2; KH<sub>2</sub>PO<sub>4</sub>, 1.2; cocaine, 0.03; corticosterone, 0.03; propranolol, 0.001; ascorbic acid, 0.1; and indomethacin, 0.01). The aortas were dissected free from extraneous tissue and then a cross sectional ring approximately 3 mm in length was cut from the most proximal segment. The aortic rings were suspended vertically in 10 ml tissue baths and bathed in Kreb's solution maintained at 37°C and constantly aerated with a 95% O<sub>2</sub> and 5% CO<sub>2</sub> gas mixture. A resting tension of 1 g was applied to each aortic ring and thereafter periodically readjusted to maintain a 1 g resting tension throughout the duration of the assay.

15 Urinary bladders were emptied and isolated from rabbits. Bladders were dissected free from extraneous tissue and then a cross sectional ring of bladder neck tissue was cut above the urethra to approximately one third of the way up the bladder. The bladder neck was cut parallel to the longitudinal muscle fibers to give flat section of muscle tissue and then the flat section was cut parallel to the longitudinal muscle to give several flat strips. Strips of bladder tissue were suspended vertically in 10 ml tissue baths and bathed in Kreb's solution maintained at 33°C and constantly aerated with a 95% O<sub>2</sub> and 5% CO<sub>2</sub> gas mixture. A resting tension of 5 g was applied to each urinary bladder strip. The strips were 20 allowed to relax to a resting tension of 1 g and thereafter periodically readjusted to maintain the 1 g resting tension throughout the duration of the assay.

25 The aortic ring or urinary bladder strip preparations were allowed to equilibrate for 60 minutes during which period the bath solution was replaced every 15 minutes. The tissue was then exposed to bath solution containing norepinephrine (0.1 to 10  $\mu$ M) and once a steady state contraction was produced the tissue was exposed to bath solution free of norepinephrine, replacing the solution twice every 5 minutes for 30 minutes. The aortic rings were exposed to norepinephrine and the urinary bladder strips to phenylephrine in a cumulative concentration fashion. That is, the isolated tissue was exposed to bath solution containing a threshold concentration of either norepinephrine or phenylephrine until a steady state contractile response was attained and then the concentration of agonist was cumulatively increased by 0.5 log increments until a maximal or near maximal response was attained. Norepinephrine produced a concentration-dependent,  $\alpha_1$ -adrenoceptor mediated contraction of the aortic rings. Phenylephrine produced a concentration-dependent,  $\alpha_1$ -adrenoceptor mediated contraction of the urinary bladder strips.

30 The tissue was then exposed to solution free of agonist, replacing the solution twice every 5 minutes for 30 minutes. After baseline tension was established and readjusted to 1 g, the tissue was exposed to bath solution containing the test compound, replacing the solution every 15 minutes for 60 minutes. In the presence of the test compound, the tissue again was exposed to either norepinephrine or phenylephrine in a cumulative concentration fashion, increasing the agonist concentration until a maximal or near maximal response was achieved.

35 The concentration ratio (CR) of agonist necessary to produce equiactive responses in the absence and presence of the test compound was determined.

Relying on the concentration ratio, the assay concentration (molar) of the test compound, and the relationship:

40

$$pA_2 = -\log \frac{[test\ compound]}{CR - 1}$$

45 the negative log of the dissociation constant (pA<sub>2</sub>) for each test compound at  $\alpha_1$ -adrenoceptors were estimated for both aortic tissue and urinary bladder tissue.

50 Proceeding as in Example 38, compounds of Formula I were tested and found to selectively inhibit the  $\alpha_1$ -adrenoceptor mediated contractions of rabbit, isolated urinary bladder smooth muscle. In contrast, prazosin, an  $\alpha_1$ -adrenoceptor antagonist that has been proscribed for treating BPH, selectively inhibited the  $\alpha_1$ -adrenoceptor mediated contractions of rat, isolated aortic smooth muscle.

EXAMPLE 39 *$\alpha_1$ -Adrenoceptor In Vitro, Functional Assay in Tissue Isolated from Human*

55

The following describes *in vitro* assays for measuring the relative effect of test compounds on  $\alpha_1$ -adrenoceptor mediated contractions of human, isolated arterial and urinary bladder smooth muscle.

Human arterial blood vessels were obtained post-mortem and immediately immersed in cold physiological saline solution. Within 24 hours of removal the isolated arterial tissue was placed in Krebs' solution (comprising in mM con-

centrations: NaCl, 118.5; NaHCO<sub>3</sub>, 25; dextrose, 5; KCl, 4.8; CaCl<sub>2</sub>, 2.5; MgSO<sub>4</sub>, 1.2; KH<sub>2</sub>PO<sub>4</sub>, 1.2; cocaine, 0.03; corticosterone, 0.03; propranolol, 0.001; ascorbic acid, 0.1; and indomethacin, 0.01). The arteries were dissected free from extraneous tissue and then cut into cross sectional rings approximately 3 mm in length. The arterial rings were suspended vertically in 10 ml tissue baths and bathed in Kreb's solution maintained at 37°C and constantly aerated with a 95% O<sub>2</sub> and 5% CO<sub>2</sub> gas mixture. A resting tension of 1 to 1.5 g was applied to each ring and thereafter periodically readjusted to maintain a 1 g resting tension throughout the duration of the assay.

Human prostatic and bladder neck smooth muscle tissue was obtained following radical cystoprostatectomies or radical prostatectomies and immediately immersed in Krebs' solution. The prostatic and bladder tissue was dissected free from extraneous tissue and then strips of tissue 0.8 to 1.2 cm in length and 3 to 5 mm in width were cut and suspended vertically in 10 ml tissue baths and bathed in Kreb's solution maintained at 37°C and constantly aerated with a 95% O<sub>2</sub> and 5% CO<sub>2</sub> gas mixture. A resting tension of 0.75 to 1 g was applied to each muscle strip and thereafter periodically readjusted to maintain a 1 g resting tension throughout the duration of the assay.

The arterial ring and prostatic and bladder neck strip preparations were allowed to equilibrate for 60 minutes during which period the bath solution was replaced every 15 minutes. The tissue was then exposed to bath solution containing norepinephrine (1 to 10  $\mu$ M) and once a steady state contraction was produced the tissue was exposed to bath solution free of norepinephrine, replacing the solution twice every 5 minutes for 30 minutes. The arterial ring and prostatic and bladder neck Strip preparations were exposed to norepinephrine in a cumulative concentration fashion. That is, the isolated tissue was exposed to bath solution containing a threshold concentration of norepinephrine until a steady state contractile response was attained and then the concentration of norepinephrine was cumulatively increased by 0.5 log increments until a maximal or near maximal response was attained. Norepinephrine produced a concentration-dependent,  $\alpha_1$ -adrenoceptor mediated contraction of the arterial ring and of the prostatic and bladder neck strip preparations.

The tissue was then exposed to solution free of norepinephrine, replacing the solution twice every 5 minutes for 30 minutes. After baseline tension was established and readjusted to 1 g, the tissue was exposed to bath solution containing the test compound, replacing the solution every 15 minutes for 60 minutes. In the presence of the test compound, the tissue again was exposed to norepinephrine in a cumulative concentration fashion, increasing the norepinephrine concentration until a maximal or near maximal response was achieved.

The concentration ratio (CR) of norepinephrine necessary to produce equiactive responses in the absence and presence of the test compound was determined. Relying on the concentration ratio, the assay concentration (molar) of the test compound, and the relationship:

30

$$pA_2 = -\log \frac{[\text{test compound}]}{CR - 1}$$

35 the negative log of the dissociation constant (pA<sub>2</sub>) for each test compound at  $\alpha_1$ -adrenoceptors were estimated for the arterial ring and prostatic and bladder neck strip preparations.

Proceeding as in Example 39, compounds of Formula I were tested and found to selectively inhibit the  $\alpha_1$ -adrenoceptor mediated contractions of human, isolated prostatic and bladder neck smooth muscle. In contrast, prazosin non-selectively inhibited the  $\alpha_1$ -adrenoceptor mediated contractions of both human, isolated prostatic/bladder neck smooth 40 muscle and isolated arterial smooth muscle.

##### Rat *In Vivo*, Blood Pressure Assay

45

The following describes an *in vivo* assay for measuring the effect of test compounds on blood pressure in normotensive and spontaneously hypertensive rats.

Normotensive or spontaneously hypertensive rats (0.25 to 0.45 kg) were fasted for 18 hours and anesthetized with ether. The right femoral vein was isolated and cannulated with a fluid filled polyethylene cannulae for bolus administration of test substances. The right femoral artery was isolated and cannulated with a fluid filled polyethylene cannula connected to an external pressure transducer for monitoring mean arterial blood pressure (MAP).

The rats were placed in restrainers and allowed to recover from anesthesia. Following a 30 minute period for stabilization, test compounds or vehicle were administered, i.v., and blood pressure was monitored continuously for at least 4 hours post-administration.

55 Proceeding as in Example 40, compounds of Formula I were tested and found to be considerably less potent than prazosin at producing blood pressure lowering effects.

Example 41Rat *In Vivo*, Tilt-Response Assay

5 The following describes an *in vivo* assay in normotensive rats for measuring the propensity of test compounds to inhibit the reflex maintenance of basal blood pressure levels in response to vertical tilt.

10 Normotensive rats (0.25 to 0.45 kg) were fasted for 18 hours and anesthetized with ether. The right femoral vein was isolated and cannulated with a fluid filled polyethylene cannulae for bolus administration of test substances. The right femoral artery was isolated and cannulated with a fluid filled polyethylene cannula connected to an external pressure transducer for monitoring mean arterial blood pressure (MAP).

15 The rats were restrained in a supine position and allowed to recover from anesthesia. Following a 30 minute period for stabilization, test compounds or vehicle were administered, i.v., and blood pressure was monitored continuously while the rats were tilted vertically at 30 to 60 degrees from supine at 15, 30 and 45 minutes post-administration.

20 Proceeding as in Example 41, compounds of Formula I were tested and found to be considerably less potent than prazosin at inhibiting the reflex maintenance of basal blood pressure levels in response to vertical tilt.

Example 42Dog *In Vivo*, Blood and Intraurethral Pressure Assay

20 The following describes an *in vivo* assay for measuring the relative effect of test compounds on hypogastric nerve stimulation-induced increases in intraurethral pressure and phenylephrine-induced increases in diastolic blood pressure in anesthetized dog.

25 Mongrel dogs (10 to 20 kg) were fasted for 12 to 18 hours and anesthetized with pentobarbital sodium (35 mg/kg, i.v.). An endotracheal tube was inserted and thereafter the lungs were mechanically ventilated with room air. The right femoral vein was isolated and cannulated with two polyethylene cannulae, one for the administration of a continuous infusion of pentobarbital sodium (5 to 10 mg/kg/hr) and the other for bolus administration of test substances. The right femoral artery was isolated and cannulated to the abdominal aorta with a fluid filled polyethylene cannula connected to an external pressure transducer for monitoring diastolic aortic pressure (DAP). The bladder was exposed via a ventral midline abdominal incision and emptied of urine through a 22 gauge needle. The bladder was cannulated through a stab incision with a water filled balloon catheter connected to an external pressure transducer for monitoring prostatic intraurethral pressure (IUP). The right hypogastric nerve (HGN) was carefully isolated and attached to a Dastre's electrode for nerve stimulation.

30 The preparation was allowed to stabilize for a least 30 minutes and must have had a stable basal IUP for not less than 15 minutes prior to commencement of the assay protocol. The HGN was stimulated (20-50 V, 10 Hz, 10 msec pulse train for 10 sec) to induce a measurable increase in IUP and then phenylephrine (PE) was administered by bolus injection (0.5 to 0.6 µg/kg, i.v.) to induce a measurable increase in DUP. The HGN stimulation and PE bolus injection were repeated every 5 minutes until three consecutive reproducible increases in IUP and DAP were achieved. Vehicle (0.1 to 0.3 ml/kg) was administered and 20 minutes later the HGN stimulation and PE bolus injection were repeated. 40 Test compound was then administered and 20 minutes later the HGN stimulation and PE bolus injection were repeated. Test compound was administered approximately every 20 minutes, increasing the dose until maximal or near maximal inhibition of the increases in IUP and DAP was attained.

45 Proceeding as in Example 42, compounds of Formula I were tested and found to selectively inhibit the HGN stimulation-induced increases in IUP. In contrast, prazosin inhibited increases in IUP and DAP in a similar fashion.
